What we found interesting

`#! /usr/bin/env python3`

A filename can hide a missing content rule.

CONTENT ONLY

No filename hint

`text/plain`

WITH script.py

Same file content
Python filename hint

`text/x-python`

Without the single-space rule. After the fix, both return text/x-python.

What we learnt

Test both detection modes

Check content alone, then add a filename.
A filename can hide a missing content rule.

Test different inputs

Check Python, Shell and boundary cases.
Review suggestions can reveal gaps.

Follow existing conventions

Use the existing pattern of two literal rules:
no space and exactly one space after #!.

Keep fixes focused

Reproduce first, then compare the same tests.
Change the relevant rules and their tests.
